Executive Summary

While the U.S. set a new coal production record in 1998, Utah fell short of its all-time high set two years earlier by about half a million tons, though it did slightly better than the previous year. The U.S. produced 1.11 billion tons of coal, the fifth consecutive year that production exceeded the one-billion-ton mark. Utah produced 26.6 million tons of coal which was the second highest production level ever. The U.S. exported 77.2 million tons of coal in 1998, which was lower than the previous three years, while Utah exports were also lower than the previous three years' and came in at 2.7 million tons. The value of coal produced in Utah was \$474 million in 1998.

Utah distributed 27 million tons of coal in 1998, the second highest ever. Electric utility consumption outside of Utah contributed significantly to this increased distribution, by 2 million tons, while industrial consumption outside of Utah increased by more than 0.5 million tons. During 1999, production should pass the 27 million ton mark and set a new all-time record.

Utah's coal mines remain the most productive underground mines in the U.S. Productivity at just under two tons per miner-hour (tpmh) in 1980 and 1981, has been on the rise ever since, reaching new highs almost every year. In 1996 Utah's mines failed to achieve a new record partly

because of the start-up and development of the Willow Creek mine. In addition, production per miner hour in 1997 fell below that of 1996's due to other difficulties encountered in the Willow Creek mine and the shortage in the rail transportation. During 1998 Utah achieved the second highest productivity with 6.19 tpmh, a figure only exceeded in 1995. Of note, the industry expects another productivity record in 1999.

Utah's high productivity is largely credited to excellent management, a capable engineering and geological staff, a high degree of mechanization, and a highly skilled workforce. These factors, in conjunction with high seam thickness and favorable geology, have led to more competitive coal prices for Utah coal which, in turn, have enhanced and guaranteed the success of the state's coal industry.

Electric utilities consumed the bulk of Utah's coal production. The Hunter, Huntington and Carbon plants of PacifiCorp's Utah Power and Light (UP&L), and Intermountain Power Agency's (IPA) Intermountain Power Plant (IPP), purchased 12.8 million tons and consumed 12.9 million tons in 1998. Together these four plants purchased about half of all Utah production, making the electric utility sector the state's best coal customer.

Deseret Generation and Transmission's (DG&T) Bonanza plant consumed 1.7 million tons of Colorado coal, but did not purchase any from Utah. Also in 1998, electric utilities and cogeneration plants outside of Utah consumed 7.7 million tons of Utah coal. Altogether, electric utilities consumed 77.4 percent of the coal produced in Utah. Including those volumes exported to the Pacific Rim (Japan, Korea, and Taiwan), electric utilities consumed 87.6 percent of all the coal produced in Utah.

During 1998, Utah purchased and consumed various amounts of coking coal (1.1 million tons) from outside the state. These imports were required since Utah ceased production of metallurgical coal in 1994.

In 1998, industrial coal consumption was Utah's second largest consuming sector. Kennecott consumed roughly two-thirds of the 0.68 million tons of Utah's industrial coal production. Geneva Steel and various cement and lime plants in Utah consumed the remaining third. Out-of-state industrial consumption amounted to 2.75 million tons in 1998 and was used primarily by chemical and cement plants in California and cement plants in Nevada. About 0.27 million tons went to the other mountain states and 30,000 tons to Illinois. Far behind exports, the third consuming sec-

1998 Utah Coal Production

tor, residential and commercial customers consumed almost 0.3 million tons of Utah coal.

Production of coal in Utah reached more than 26.6 million tons, the second highest production level in 129 years, exceeded only by the 1996 level of 27.1 million tons. Gross production topped 26,755,000 tons and net production came in at 26,600,000 tons (See Appendix, Tables 1 and 2).

MINER PRODUCTIVITY

Production in 1998 increased over 1997 levels by 0.65 percent and employment decreased by more than 6.7 percent, which caused productivity to rise by more than 11 percent. Miner productivity increased from 12,639 tons per year in 1997 to 13,641 tons per year in 1998. The number of days worked per year rose from 247 to 248, thereby increasing coal production per miner per day from 51.3 tons to 55.1 tons. Productivity per miner hour also increased from the recently adjusted figure of 5.57 tons per miner hour to 6.19. This increase could be explained by the start up of the longwall panel in Cyprus Plateau's Willow Creek mine and also by higher productivity achieved by Genwal and Sufco.

During 1998, a total of 1,950 miners produced 26,600,000 tons of coal. Working an aver-

age of 248 days per year (483,600 miner days), miners produced an average of 6.19 tons per hour (See Appendix, Table 1), a figure about 11.1 percent more than 1997's 5.57 tons per hour. (Note: those figures are based on net production). On the basis of gross production, productivity was slightly higher.

MAJOR COAL FIELDS

Again, the Wasatch Plateau coal field was the major coal producer in 1998 (See Appendix, Maps 1 and 2). More than 85 percent of Utah's 1998 coal production (22.7 million tons) came from this field while the Book Cliffs accounted for the remaining 14.6 percent (3.9 mil-

Utah Coal Industry Production, Employment, Productivity and Prices

	Production Million Short Tons	Employment No. of Employees	Productivity Tons/Miner Hour	Prices \$/Ton

1999 values are forecast

lion tons). The Emery coal field, the only other significant producer in recent years, produced no coal between 1992 and 1998. During 1999, the Wasatch Plateau coal field is expected to produce a record of 23.1 million tons, representing 83.7 percent of total production. In contrast, about 4.5 million tons or 16.3 percent of Utah's coal production is expected to come from the Book Cliffs coal field. For the eighth year in a row, no production is likely from the Emery coal field (See Appendix, Table 3).

COAL PRODUCTION BY COUNTY

On a county basis, during the 1960s and 1970s Carbon produced much more than Emery with Sevier producing small amounts. During the last decade, coal production from Emery surpassed that of Carbon with Sevier showing a significant gain. During this decade Emery's production at times was two to three times as much as Carbon with Sevier gaining on Carbon.

Skyline mine, which is now owned by Canyon Fuel Corp., and Starpoint mine of Cyprus Plateau shifted production from leases in Carbon to those in Emery County. The balance of coal production by county shifted dramatically from Carbon to Emery since these two mines combined accounted, at the time, for about 27 percent of total coal production. The actual shift by both mines started in 1991, became more pronounced in 1992, and was near-

ly completed in 1993 (See Appendix, Table 4). Over time, however, Skyline mine production started shifting back to Carbon County, resulting in more production from Carbon County leases than those of Emery County. Compared to the Skyline mine, the Starpoint mine shift was more accelerated, becoming even more pronounced when Cyprus Plateau moved most of its coal operation from the Starpoint mine to the Willow Creek mine, located entirely in Carbon County. Sevier county production is still increasing and within the next two years should surpass the 6 million ton mark.

FEDERAL, STATE, AND COUNTY LANDS

Coal mined from federal leases during 1998 came in at 25.0 million tons. Its contribution as a percentage of total state production was about 1.4 percent below 1997 figures, representing the fourth highest percent of production from federal lands. During the past three years the percentage of production was slightly higher.

State lands production had not reached the one-million-ton mark since 1980. In 1992, production easily surpassed this level with 1.384 million tons of coal produced and again in 1993 with a record of 1.682 million tons of production. In 1994, production from state lands decreased to 1.227 million tons, a figure still higher than at any time in the 1980s. During 1995, production from state lands was cut to less than half of the 1994 level. In 1996 it was lower by

more than 125,000 tons than in 1995 and in 1997 it decreased again by 107,000 tons to a new low of 339,000 tons.

During 1998 production from state lands slipped further to 297,000 tons. As a percentage of total production, state lands' production has historically only accounted for between 1 to 5 percent, which increased to above 6 and 7 percent in 1992 and 1993; in 1994, it fell back to 5 percent; in 1995 to 2.3 percent; in 1996 to 1.6 percent; and in 1997 to 1.3 percent. During 1998, state land production at 1.1 percent registered the lowest percentage production level in more than two decades.

Production from county lands has always been minimal and erratic. During 1998, county-owned lands produced only 37,000 tons.

FEE LANDS

For the first time in a decade, coal production from fee lands slipped below 2 million tons (1.735 million tons) in 1992. In 1993, production decreased again by 50 percent to 826,000 tons, dropping further in 1994 to 415,000 tons or 1.7 percent of total production. In 1995 production moved up by 11 percent to 461,000 tons or 1.8 percent of total production, in 1996, fee lands came in at 614,000 tons or 2.3 percent of total production and again in 1997 there was a further increase to 928,000 tons or 3.5 percent of total production. During 1998, production from fee lands went up to 4.9 percent of

the total production while, on a tonnage basis, production increased by more than 41 percent (from 928,000 to 1.312 million tons) as compared to 1997. By contrast, coal produced from fee lands in 1983 represented almost 40 percent of total production (See Appendix, Table 5).

LONGWALL PANELS AND CONTINUOUS MINERS

During 1998, seven operating longwall panels accounted for 75 percent of production or 20.01 million tons. This amounted to an average of more than 2.86 million tons of coal production per panel per year. Twenty-four continuous miners produced a total of 6.595 million tons of coal for an average of 274,790 tons per machine per year. In recent years, however, some machines have produced between 400,000 to nearly 600,000 tons per year.

Utah Coal Markets: Distribution of Utah Coal

Distribution of Utah coal, which from 1990 to 1993 had been relatively unchanged and remained within 1 percent of 21.6 million tons, jumped by 6.9 percent in 1994 from 1993 levels. Between 1994 and 1995, distribution increased by 8.5 percent and increased another 9.3 percent by 1996. In 1997 however, distribution fell back to the 1995 level. Distribution of coal hit an all-time high of 23.44 million tons in 1994 and set yet another record of 25.97 million tons in 1995, but 1996 distribution surpassed these levels with 27.82 million tons, an increase of more than two million tons, however, in 1997 it stood at 25.45 million tons.

During 1998 distribution passed all previous records, with the exception of 1996, and stood at 26.97 million tons. Distribution of Utah coal to consumers in Utah reached 13.7 million tons, the fourth highest rate of Utah coal consumption in the 129 years of Utah's coal industry. Distribution to consumers in other states totaled 10.3 million tons, about 2.4 million tons more than in 1997, while overseas exports amounted to 2.7 million tons, about 0.8 million tons less than the 1997 export level.

ELECTRIC UTILITY MARKETS

Over two decades ago, electric utility consumption of coal surpassed the combined

consumption levels of industrial coal and coke plant coal and became the top market for Utah coal operators. Today about 77.4 percent of Utah's coal production is consumed to generate electricity in Utah and other states. Including exports, about

tons over the previous year's level.

Distribution by State

About 55.4 percent of this shipment went to coal-fired power plants and cogeneration facilities in Nevada and California. Illinois and Tennessee re-

1998 Distribution of Utah Coal by Consuming Sector

87.6 percent of Utah's coal production is consumed to generate electricity. Which amounts to 86.2 percent of Utah's total coal distribution.

Out-of-State Markets

Distribution of Utah coal to out-of-state markets during 1998 increased by about 36.6 percent from the 1997 level. Utah shipped a total of 7.7 million tons to out-of-state electric utility and cogeneration customers¹, an increase of 2.1 million

tons over the previous year's level. received the lion's share of Utah's electric utility coal to the east. Canyon Fuel and White Oak were the major shippers to Illinois while White Oak, Genwal, and Canyon Fuel supplied the entirety of the shipment to Tennessee partly in compliance with the contract detailed in the 1994 Coal Report. The total shipment to these two states increased considerably from 1997 levels (See Appendix, Table 6).

Distribution to Nevada

In Nevada, four electric power generation facilities burn

¹ Editor's Note: The Energy Information Administration, in adhering to a more restricted definition of "electric utility" and "other industrial" coal consumption, classifies cogeneration consumption under the definition of "other industrial" coal. For purposes of this report, coal shipped for consumption to cogeneration

facilities is considered "electric utility" consumption, since its main purpose is to generate electricity for sale.

bituminous or subbituminous coal. Three of these plants, Nevada Power Company's Reid Gardner plant, Sierra Pacific Power Company's North Valmy plant, and Pinon Pine Power plant, burn Utah coal.

In 1998, the Reid Gardner plant, rated at 636 megawatts (MW), purchased a total of 1.8 million tons and burned 1.9 million tons for a net generation of 3,973 gigawatt hours (GWh) of electricity. Of note, all of the coal purchased by the Reid Gardner plant came from Utah.

Before 1993, Reid Gardner's four units relied almost entirely on Utah coal. One of Nevada Power's four major contracts with Utah coal producers was with ARCO, which originally supplied the coal from its Gordon Creek mines and, later, from its Trail Mountain mine. In September 1992, ARCO sold Trail Mountain to PacifiCorp, but continued to fulfill its contractual obligation to Nevada Power from its Utah stockpile and through local purchases. However, between 1993 and 1997, ARCO fulfilled the major portion of its obligation from its West Elk mine in Colorado. During 1998, Nevada Power started purchasing coal from Cyprus Plateau's Willow Creek Mine. These purchases should continue throughout 1999.

North Valmy Plant

The two units of Sierra Pacific Power Company's North Valmy plant (jointly owned with Idaho Power Company) have a combined generation capacity of 521 MW and require about 1.45

million tons of coal per year. In 1998, Utah coal shipments to the North Valmy plant totaled 1.7 million tons, which represented an increase of 56 percent over 1997 levels. Sierra Pacific did not purchase any coal from Black Butte Coal Company near Rock Springs, Wyoming as they did in previous years.

In 1998, North Valmy's two units burned 1.6 million tons of coal to generate 3,780 GWh of gross and 3,534 GWh of net electricity. During 1999, this plant is expected to consume 1.75 million tons and generate about 4,124 GWh of gross or 3,876 GWh of net electricity.

Despite consumption of some natural gas for electric generation, the coal purchased from Utah increased by more than 56 percent. However, there was no coal purchased from Wyoming.

Pinon Pine Power Plant

In September, 1991, the Department of Energy's Clean Coal Technology Programs (CCTP) identified nine projects for future development. One such project is the Pinon Pine Power plant, a 107 MW electric generation plant located at Sierra Pacific Power Co.'s Tracy Station, located 17 miles east of Reno, Nevada.

The project's main objective is to demonstrate commercial feasibility of a low-Btu gas combustion turbine fed by an air-blown, pressurized, fluidized-bed Integrated Gasification Combined Cycle (IGCC). During

August 1992 the DOE and Sierra Pacific Power Co. (SPPC) signed a cooperative agreement to carry out the project. The DOE and SPPC provided the required funding of \$308 million on an equal basis.

The core of the project is a fully conventional combined-cycle power plant capable of operation on natural gas. The M.W. Kellogg Co. provided the technology for this advanced IGCC. The company used a Kellogg Rust Westinghouse (KRW) version of the World War II vintage coal gasification technology.

The project's Environmental Impact Statement (EIS) was completed on November 8, 1994, and construction began in February 1995. In 1996, the power plant was completed and the unit went into commercial operation in December of that year.

The coal gasifier, completed in early 1997, converts coal into clean burning gas to be consumed in a General Electric combustion turbine. This unit will operate for the next four years as a demonstration unit and the cost of fuel and operation will be shared equally by the DOE and SPPC.

The unit's net design efficiency is about 40.7 percent, equivalent to a heat rate of 8,390 Btu/kWh, and is the most efficient coal-based unit in the country. Because the fuel produced by the gasifier is cleaned, the amount of NO_x and SO₂ is reduced by over 90

percent.

After this fuel is burned in the gas turbine to generate electricity, the excess heat is used to produce steam which is then used in a steam turbine generator to produce more electricity.

The unit's advanced design boosts efficiency by 20 percent over that of conventional power generators, a process which results in 25 percent less CO₂ emission for the generation of the same amount of electricity. This unit also uses 20 percent less water to generate the same amount of electricity as conventional generators, which makes it a very desirable unit in the arid region of the American West.

The IGCC is designed to consume different grades of coal. On a regular basis, central Utah operators will supply the required coal, which could amount to 320,000 tons per year. At times other coal, specifically high-sulfur coal from the Midwest, may be consumed to evaluate the technology's potential application elsewhere in the U.S. or abroad. This unit's fuel flexibility allows it to use natural gas, coal or any combination of the two for maximum fuel cost savings. The unit's other advantage is its ability to generate electricity by consuming only natural gas when the gasifier is down for repair or maintenance.

During 1996 the coal purchased for this unit was minimal and for 1997 it was just

over 10,000 tons; however, the plant operated only on natural gas during the entire year. This plant used very little coal in 1998 and it appears as though the final streamlining of the gasifier will be complete by the end of 1999.

California

About 0.84 million tons of Utah coal went to cogeneration facilities in California. The electric utility market for Utah coal in California presently includes six coal-fired cogeneration units.

Stockton California Plant

Stockton, California is the site of the first coal-fired cogeneration facility ever to burn Utah coal. This unit is operated by Air Products & Chemicals, Inc. and began commercial operation in March 1988. This 49.9 MW unit is capable of consuming 220,000 tons of coal per year to generate about 425 GWh of net electricity.

In 1998, this plant purchased 106,600 tons of coal, all of which came from Utah. The plant consumed 113,400 tons of coal to generate a total of 451 GWh of gross or 409 GWh of net electricity. Just under 32 GWh of the electricity and all of the steam by-product were used by an adjacent corn wet milling plant owned by Corn Product Co. International. Pacific Gas and Electric Co. (PG&E) purchased the remaining 377 GWh. During 1999, this plant will purchase 120,000 tons of coal and is planning to generate 430 GWh of net electricity, most of which

will be sold to PG&E.

Mt. Poso Field - West Plant

In May 1989, a second coal-fired cogeneration facility was commissioned. It is owned by Mt. Poso Cogeneration Co., a consortium of Ahlstrom Development Corp., Pacific Generation Co. and Bechtel Enterprises, Inc. This 49.9 MW plant is located in the San Joaquin Valley and is operated by Pyropacific Operating Company and Pacific Generation Company. During 1998, Mt. Poso purchased 83,000 tons of Utah coal, and burned only 33,000 tons to generate 111 GWh of gross or 103 GWh of net electricity that was sold to the California Power Exchange at market prices.

There are two reasons for the reduced consumption: 1) PG & E came to a financial agreement with Mount Poso not to produce any electricity for sale to them and 2) some petroleum coke was consumed in lieu of coal. The operations in the Mt. Poso Field-West used the steam by-product for enhanced oil recovery. During 1999, this unit will consume 143,000 tons of coal to generate 450 GWh of net electricity.

ACE Plant

The largest coal-fired cogeneration facility in California, with 96 MW of installed electric generation capacity, is owned by ACE Cogeneration Co., which is in turn owned by Ahlstrom Development Corp., Constell-

ation Holding, Inc. and the Kerr McGee Chemical Company. This unit is located in Trona, California and started operation in September 1990. North American Chemical Company's two soda ash plants adjacent to the ACE plant use the steam by-product. This unit has the capacity to burn 300,000 to 350,000 tons of coal per year to generate between 650 to 750 GWh of electricity. During 1998, the firm purchased 395,000 tons of Utah coal and burned 390,000 tons to generate 865 GWh of gross electric generation. Southern California Edison Co. purchased the net 788 GWh of electricity. This unit is expected to burn about the same amount of coal during 1999.

Rio Bravo Plants

Ultra Power, Constellation and Hadson are the owners of a twin cogeneration plant, comprised of two 38.5 MW units located in Bakersfield (Rio Bravo Poso and Rio Bravo Jasmin). Construction of this twin plant started in December 1987 and was completed in March 1990. The plant started commercial operation in September 1989 and came on-line early in 1990.

During 1998, Rio Bravo Poso purchased 87,000 tons of Utah coal, burning about 76,000 tons to generate 328 GWh of gross or 295 GWh of net electricity, which was ultimately sold to PG&E. The Rio Bravo organization used the steam by-product in its oil field for enhanced oil recovery (EOR)

operations. During 1999, this plant will consume 75,000 tons of coal and will generate 278 GWh of gross electricity.

Rio Bravo Jasmin purchased 80,000 tons of Utah coal and burned 73,000 tons to generate 321 GWh of gross or 288 GWh of net electricity which was sold to Southern California Edison. Rio Bravo oil field also used the steam by-product of this unit for EOR operations. During 1999, this plant is expected to purchase and burn about 75,000 tons of Utah coal, and generate close to the same amount of electricity as in 1998.

Energy Factor Plant

The Energy Factor plant is a cogeneration facility located in Stockton, California. This 45 MW cogeneration plant was first bought by Sithe Energy in 1990 and then sold to a partnership of National Power Company and ESI in 1993. ESI, a wholly owned subsidiary of Florida Power Company, originally backed only this transaction, but later decided to take a more active role in the plant's daily operation. This plant is now operating under the name of Port of Stockton District Energy Facility (POSDEF) Power Company L.P. The steam by-product from this plant goes to three processing facilities within the same industrial complex: California Cedar Products Company, which manufactures cedar wood products including Dura Flame logs and Cargill and Liquid Sugar, both of which import raw sugar from Hawaii and manufacture various food

products for human and animal consumption. This cogeneration unit requires up to 200,000 tons of coal per year. The coal supply contract for this company is with Oxbow Carbon and Minerals, Inc. of Colorado (previously known as Pacific Basin Resources). During 1998, this company purchased 84,000 tons of coal, all of which came from Utah. This unit consumed 90,000 tons of coal to generate 400 GWh of gross electricity with 269 GWh net generation sold to PG&E. For the foreseeable future, it is likely that all of the requirement of this unit will be supplied solely by Utah.

Shipments of coal for consumption by electric power plants in Nevada are expected to increase by 8.7 percent from the 1998 level to 3.76 million tons in 1999. During 1993, the amount of coal sold to electric utilities within the U.S. excluding Utah, Nevada and California - the main users of Utah coal - nearly doubled from 556,000 to 1.09 million tons. During 1994, this consumption reached 1.71 million tons, more than 200 percent over 1992 and about 60 percent over 1993 levels. In 1995, this consumption shot up to 3.4 million tons, which was almost twice that of 1994. In 1996 this consuming sector surpassed 3.90 million tons, an increase of nearly 15 percent over 1995, but in 1997 this consumption decreased to 2.44 million tons. During 1998 Utah had an increase of more than 40 percent to 3.44 million tons. States receiving electric utility

coal from Utah includes: Illinois (2.21 million tons) and Tennessee (1.23 million tons). During 1999, this consumption should decrease by 34 percent from 3.44 million tons to 2.26 million tons, mostly due to smaller shipments of coal to Illinois. Because of this decrease, Utah coal distributed to all other states for electricity generation is expected to decrease from 7.7 million tons in 1998 to 7.3 million tons in 1999.

Utah Markets

Utah coal consumed in Utah to generate electricity amounted to nearly 12.93 million tons in 1998, which exceeded expectations. Utah coal shipped to electric utility plants was 12.81 million tons.

Hunter Plants

PacifiCorp's Hunter units (I, II, and III), with availability of 85.33 percent and utilized availability of 98.08 percent, consumed 4.144 million tons of coal mostly from PacifiCorp's Cottonwood mine and some from its Deer Creek mine to generate 9,054 GWh of net electricity. During 1999, this plant should be working at about 99.9 percent capacity factor consuming 4.89 million tons of coal to generate 10,294 GWh of net electricity which would be about 13.7 percent above 1998.

Huntington Plants

Huntington's Units I and II, with plant availability of about 85.0 percent and utilized availability of 102.5 percent, consumed 2.914 million tons of coal produced from PacifiCorp's

Deer Creek mine to generate 6,453 GWh of net electricity. During 1999, this plant should be working at 92.0 percent availability and 99 percent utilized availability consuming 3.14 million tons of coal to generate 7,139 GWh of net electricity. This will be 10.6 percent above the 1998 generation level.

Carbon Plant

The Carbon plant, with availability of 88.27 percent and utilized availability of 95.23 percent, consumed more than 600,000 tons of coal to generate 1,289 GWh of electricity. Nearly all the coal consumed in this plant was purchased from the Genwal Coal Company. It is very likely that the capacity factor for PacifiCorp's three plants could be as much as 2 percent higher in 1999 than in 1998, and coal consumption

could increase from 7.66 to 8.60 million tons. In 1999, coal production for distribution to Utah electric utilities is likely to exceed the increase in consumption, which means that stockpiles would increase to some extent.

IPP Plants

In 1998, the Intermountain Power plant (IPP), of the Intermountain Power Agency (IPA), operated with an availability of 94.97 percent. The plant's two units, with a total nameplate capacity of 1,640 MW, burned 5.27 million tons of coal to generate 13,081 GWh for the state of California. During 1999, this plant will burn approximately 4.8 million tons of coal to generate 11,900 GWh of electricity, nearly all of which will be sold outside of Utah. All of this coal may not come from Utah as there are indications that

Distribution of Coal to Utah Electric Utilities

negotiations on coal purchase contracts with producers in Colorado had occurred during 1998. The higher availability of hydropower in the Northwest at times causes a decrease in coal burned during the spring and summer runoff. By early spring, 1999, the northwest region had considerable snow accumulation which should result in above normal runoff in the summer of 1999.

Bonanza Plant

During 1998, Deseret Generation and Transmission's (DG&T) Bonanza plant with a rated peak capacity of 420 MW, achieved an availability of 98.8 percent and a load factor of 93.7 percent. This plant consumed 1.69 million tons of Colorado coal to generate 3,429 GWh of net electricity. DG&T purchased 1.72 million tons of coal from the Deserado mine, located just 36 miles east of the Bonanza plant in Colorado. During 1999 the availability will decrease to 94 percent, though the capacity factor should remain the same and coal consumed will equal 1.78 million tons, resulting in 3,354 GWh of electricity generation.

UTAH COKING COAL MARKETS

The market for coking coal in Utah is limited to Geneva Steel Company's operations in Vineyard, Utah, which is the only integrated steel mill operating west of the Mississippi River. Located 45 miles south of Salt Lake City, the firm manufactures hot-rolled steel plate, sheet, and pipe for

markets primarily in the western and central U.S. Geneva's customers include service centers, distributors, steel processors and various end users which include: manufacturers of welded tubing; highway guardrail; storage tanks; railcars; ships; and agricultural and industrial equipment. In recent years, Geneva has undergone an extensive modernization program intended to enhance its competitive position by reducing operating costs, expanding product lines, improving quality and significantly increasing throughput capacity. With these improvements, Geneva Steel strengthened its position as a low-cost steel producer while becoming one of the industry's more environmentally advanced steel mills. The company acquired the steel mill and related facilities in a leveraged buy-out from USX Corporation in August 1987. Coal purchased by Geneva Steel to make coke totaled 0.982 million tons during 1998. The plant consumed about the same amount of coal to make coke for steel production.

As Geneva Steel improved its blast furnace productivity, coke making at the plant fell short of iron production demand. During 1998, Geneva overcame this constraint by directly purchasing 185,000 tons of coke from China, in addition to its own manufactured supply, to produce about 2.0 million tons of raw steel. To meet its requirement of low- to mid-volatile hard coking coal, Geneva Steel negotiated long term contracts

with eastern producers and a multi-year transportation contract with the Union Pacific railroad.

During 1998, Geneva bought 153,000 tons of low-volatile Pennsylvania coking coal from Cooney Brothers Coal Company of Cresson, Pennsylvania. In addition, Geneva bought 443,000 tons of high-volatile Colorado coking coal from the Somerset mine of Oxbow Carbon and Mineral, Inc. (previously known as Pacific Basin Resources) of Littleton, Colorado. This coal is from the same seam as the coal Geneva purchased from Bear Coal Company, Inc. of Somerset, Colorado during the early 1990s.

Geneva also bought and consumed 36,000 tons of mid-volatile Virginia coking coal from Knox Creek Coal Company situated just west of Richlands, which is on highway 460 and 19 in Russell County in the toe of Virginia near Graceland railroad station. This company is part of the United Coal Company.

Furthermore, Geneva purchased 106,000 tons of high quality West Virginia coking coal from Commonwealth Coal Company's War Eagle mine situated just west of Balt which is on county road 99 about 15 miles due west from Beckley in the south western part of West Virginia. In addition, Geneva obtained 225,000 tons of high quality West Virginia coking coal from Power Mountain mine of Nicholas Energy which is part of Massy Coal Company. The

Power Mountain mine – named with reference to its location – is the same as the Spartan Eagle mine – which had a reference to the coal seam mined.

Geneva also purchased 19,000 tons of mid volatile coal from Fording Coal Company's Fording Eagle mine located in the southeast corner of British Colombia just 70 miles across the border.

During 1999, Geneva will purchase about 662,000 tons of coal and a very small amount of coke to produce 1.4 million tons of raw steel.

OTHER INDUSTRIAL COAL MARKETS

Out-of-state Markets

Since 1989, when shipments of coal to other states for industrial consumption peaked at 2.4 million tons, consumption for this market sector has been declining, reaching only 2 million tons in 1992. During 1993, shipments increased for the first time in four years and in 1994 this trend continued as six operators shipped 2.32 million tons of industrial coal to ten states outside Utah. In 1995, there was a slight increase to 2.4 million tons but in 1996 this consumption decreased slightly to 2.34 million tons and in 1997 there was a further decrease to 2.16 million tons. During 1998 this consumption hit an all time high of 2.75 million tons. The largest recipient of industrial coal was California's chemical and cement manufacturing plants

with more than 78.7 percent of all industrial coal shipped from Utah. Nevada received 287,000 tons for use mainly in cement plants. This level was 62

Montana purchased only 3,000 tons. In total, out-of-state industrial consumption should increase to 2.76 million tons in 1999.

1998 Distribution of Utah Industrial Coal by State
Thousand Short Tons

percent greater than the 177,000 tons consumed in the previous year. Shipments to Arizona amounted to 116,000 tons. Washington shipments ranked fourth with 79,000 tons followed by Idaho which purchased 70,000 tons. Hawaii, which purchased 21,000 tons in 1997, did not purchase any Utah coal in 1998. Lastly,

Utah Markets

In 1998, industrial consumption of coal in Utah increased by 2.3 percent to 680,000 tons from 665,000 tons the previous year. Kennecott Copper consumed more than 66 percent of the total to generate electricity.

Kennecott Copper

During 1998, Kennecott purchased 452,000 tons of Utah coal and consumed 447,000 tons, along with 177 million cubic feet of natural gas, to generate 936 GWh of gross electricity or 858 GWh of net electricity. The coal purchase in 1998 increased by nearly 12 percent in comparison with the previous year's figure.

In 1999, Kennecott's coal-fired electric generation will jump 11 percent. Total coal consumption will amount to 473,000 tons.

Cement Manufacturers

Prior to 1995, Utah's cement manufacturers suspected increasing demand, due to the growth of the housing industry, and began to expand their production capacity. Production capacity also increased due to the I-15 reconstruction project and various other state and county road expansions. Both Holnam and Ashgrove started to increase production prior to and during 1996 and by 1997 were producing considerably more cement. During 1998 both had reached the highest level of production. Together they consumed 166,000 tons of Utah coal during 1998.

Holnam

The Devil's Slide plant of Ideal Basic Industries, Inc., a leading cement producer based in Denver, Colorado, has been a part of Holnam since 1986. A series of mergers and acquisitions established Holnam, Inc., as one of the largest cement companies in North America. Dundee Cement Co., Santee Cement Co., Northwestern

States Portland Cement Co., Ideal Basic Industries and United Cement Co. have all been brought together under the Holnam banner. Holderbank controls 89.3 percent of Holnam's common stock and, in the consolidation process, Holderbank's share in St. Lawrence cement was brought into Holnam, which now holds a 60 percent interest in St. Lawrence.

In 1986 Holderbank acquired a 66 percent interest in Ideal Basic Industries, Inc., which had encountered some financial difficulties and required financial restructuring. The nine-plant Ideal Basic system fit in well with the Dundee Cement Co. system, offering new markets to the West, Southwest, and Mid-Central regions of the U.S. The whole establishment, comprised of 19 cement plants and 113 distribution terminals in most U.S. states and three provinces of Canada, is now referred to as Holnam.

The Devil's Slide plant switched from Wyoming coal to natural gas in 1991 and continued to burn natural gas until August 1992. In that year, the price of natural gas increased and coal consumption became more economical. During the remainder of 1992, the Devil's Slide plant used 27,000 tons of coal. A significant event occurred when this plant converted from natural gas to coal; it did not automatically switch to Wyoming coal as it had in the past but, instead, started using Utah coal.

During 1993, the Devil's Slide plant purchased 60,000 tons of coal, 40,000 tons of which came from Utah and the remainder from Wyoming. In 1994 the plant's purchase of Utah coal increased to 59,000 tons; while purchasing only 4,000 tons of additional coal from Wyoming. By 1995 the plant purchased only Utah coal (25,000 tons) and used 30,600 tons of coal in total. Some of this coal came from the stockpile and was used with natural gas for summer use and treaded tires and diaper plastics (materials obtained from the Kimberly Clarke plant in Ogden) to produce 351,000 tons of cement. In 1996 this plant purchased and consumed 29,000 tons of Utah coal plus some natural gas, tires from Salt Lake Treading Co., and more diaper plastics to produce 350,000 tons of cement. During most of 1997, Devil's Slide plant purchased 26,000 tons of Utah Coal which was consumed in the old plant along with 0.623 billion cubic feet of natural gas as well as 6,100 tons of tires and 4,200 tons of diaper plastics to produce 243,000 tons of clinkers. On November 11, 1997, the new plant commenced operations and did not consume any coal but consumed 0.2 billion cubic feet of natural gas along with 700 tons of tires and 900 tons of plastic to produce 46,000 tons of clinkers to the end of the year. During 1998 the plant purchased 57,000 tons of coal and burned 56,000 tons along with 292 million cubic feet of

natural gas, more than 4,000 tons of tires and 6,000 tons of plastic material to produce 544,000 tons of clinkers.

For 1999 this plant will purchase and burn more than 55,000 tons of Utah coal to produce well over 575,000 tons of clinker. Some natural gas (181 million cubic feet) will also be consumed along with similar amount of treaded tires and diaper plastics.

Ashgrove Cement

During 1996 Ashgrove Cement expanded operations to increase clinker production by 20-25 percent. The project actually started in 1995 and was completed in the early fourth quarter of 1996. Incorporation of the project into the operation took place in May and June of 1996 when the total clinker producing operation was shut down. During the remainder of 1996 and early 1997 Ashgrove solved the expansion problems but the production did not reach the intended target until June 1997 when Ashgrove decided to increase the capacity of the main fan. Ashgrove also added a 30,000 ton cement silo for more storage capacity. Throughout 1997 additional changes were made improving the clinker production capacity.

With completion of a new waste oil refining unit north of Salt Lake City, the economics of burning waste oil are now unfavorable. Further changes in the configuration of the clinker production system has also made using tires more difficult. During 1998 Ashgrove pur-

chased 109,000 tons of coal, and burned almost the same amount, in addition to 134,000 gallons of diesel fuel, to produce 789,000 tons of clinkers which went into making 806,000 tons of cement. This cement plant is now at peak of production and should remain at this level of production and coal consumption for the foreseeable future.

Several industrial firms, ranging from Geneva Steel to lime plant operations, purchased nearly 68,000 tons of coal. Industrial coal consumption in Utah should remain around 690,000 tons per year for at least the next two years.

RESIDENTIAL AND COMMERCIAL COAL MARKETS

Out-Of-State Markets

Since the mid-1980s, when consumption stabilized at about 300,000 tons per year, demand for residential and commercial coal has been on the decline. By 1990, it stood at only 59,000 tons. In 1991, sales to the residential and commercial sector increased to 76,000 tons and in 1992, to 81,000 tons. During 1993, out-of-state consumption jumped by 63 percent to 134,000 tons; by 1994, this sector consumed 308,000 tons. This unusual increase was due mainly to consumption of 193,000 tons by Illinois, which did not buy any Utah coal in 1995. This consumption decreased to 51,000 tons in 1996, its lowest ever, though increasing to 60,000 tons in 1997. By 1998

this sector increased to 82,000 tons. Idaho and Washington bought larger quantities. In contrast, Colorado purchased a relatively small amount (See Appendix, Table 6). Consumption by the residential and commercial sectors in these states will probably remain stable in the short term, though with some fluctuations. For 1999, a slight decrease is very likely.

Utah Markets

During 1998, residential and commercial coal consumption in Utah increased by 120 percent to 212,000 tons. This level of consumption was by far the highest in the past 5 years.

In some counties such as Emery, Wayne, Millard, Juab, Sanpete, Sevier and Carbon approximately 15 to 20 percent of homes are heated with coal. In comparison, the Wasatch Front counties of Salt Lake, Utah, Weber and Davis consume very little coal for home heating. Commercial consumption of coal for space heating in Davis, Weber and Salt Lake counties is also low.

There are two elements that affect residential and commercial consumption: environmental standards set by various air quality control agencies and the cost of fuel. When the price of natural gas is low there is a strong tendency on the part of the residential and commercial sectors to consume more natural gas but, as the price of natural gas increases, the less expensive coal becomes more attractive in spite of environ-

mental considerations. Utah coal producers might not see an increase in consumption of Utah coal by residential and commercial markets unless the price of natural gas increases again. For 1999, coal consumption will

Mill. Since February of 1994, when the coal supply contract between Geneva and Sunnyside Reclamation and Salvage Company expired, Utah has relied entirely on out-of-state coking coal and coke for

of coal from Utah operators. In 1999, imports will remain the same as Bonanza continues its higher level of electric generation, while Geneva Steel's coal imports should fall short of the previous year by 32 percent.

Utah Coal Exports to Pacific Rim Countries Thousand Short Tons

1999 value is forecast

increase to the highest level of the past two decades within the state of Utah, but could remain the same or slightly decrease in states outside of Utah, resulting in higher total consumption than in 1998.

Coal Imports

Utah imports coal for coking applications and coal-fired power generation in Uintah County. There are no imports bound for the industrial, residential, or commercial sectors. In 1998, companies operating in Utah imported 2.7 million tons of coal.

Utah previously imported low to mid-volatile hard coking coal to mix with its own high volatile coking coal for the Geneva Steel

steel production, thus accounting for the major increase in the amount of imported coal to Utah. Imports of industrial coal to Utah were used primarily at Holnam's Devil's Slide plant located in Morgan near the Wyoming border. However, this plant's consumption is now being met by Utah coal, and further imports were ceased in favor of Utah coal. The only other coal imports to Utah are about 1.7 million tons of electric utility coal used in DG&T's Bonanza plant.

The Bonanza plant purchased 1.73 million tons of coal from the Deserado mine in Colorado for its 1998 electric generation, with no purchases

The Devil's Slide plant purchased a little more than 9,000 tons of Wyoming coal when it switched from natural gas during the second half of 1992. During 1994, this plant purchased 4,000 tons of industrial coal from Wyoming. During the 1995-98 period it did not purchase any out-of-state at all. Furthermore, Holnam is not expected to purchase any Wyoming coal in 1999.

There is no indication that coal will be imported into Utah for use by the residential and commercial sector in 1999. Altogether, the imports of coal into Utah are expected to decrease to 2.4 million tons in 1999 from 2.7 million tons in 1998.

OVERSEAS EXPORTS

During 1998 exports fell to 2.7 million tons, to about one half of the 1996 export level.

Utah is uniquely situated in the coal export market. Its low cost, low sulfur and high Btu coal is closer to West Coast ports for shipment to Pacific Rim countries than any other U.S. coal source. In the past U.S. coal exceeded the cost of other coals in the Pacific Rim region, despite offering several quality advantages such as high Btu and low sulfur content. In addition to the coal quality, U.S. coal producers are considered

the most reliable, an attribute of Utah's coal that Pacific Rim countries value very highly.

The cost of production and price of Utah coal steadily decreased over the past decade, largely due to increased productivity. As a result, Utah coal is nearly as competitive on a price-per-million Btu basis as coal produced in other countries. By 1995, Utah coal became quite competitive with Australian and other coals in the Pacific Rim. In 1996 the price of coal stayed relatively flat in the Pacific Rim market; indeed, a \$0.10 drop per ton of coal did not have a significant effect. During 1997 Pacific Rim consumers managed to extract a \$2.50 per ton concession from the Australian producers. Utah coal producers were hoping to keep their concession below the \$1.00 level but were not totally successful in that endeavor. The level of concession ultimately matched the average of what the Australian coal producers agreed to and what Utah coal producers were hoping to give.

While the Pacific Rim market was one of the fastest growing markets in the world prior to 1997, the financial problems which surfaced during 1997 signaled a downturn in consumption and therefore the generation of electricity. This trend continued during 1998 and Utah's exports to the Pacific Rim was also down 22 percent from the previous year.

For 1999 this market should show some sign of strengthening and the export level of Utah coal

to Pacific Rim could increase by a quarter million tons.

Activities of Utah Coal Operators

PacifiCorp Energy West

In 1998, PacifiCorp produced a total of 7.159 million tons of coal from their Central Utah underground mines. The Deer Creek mine produced 3.748 million tons of coal while the Trail Mountain mine produced 3.411 million tons. Each of the two mines employed two continuous miner sections for development and one longwall section, which produced the majority of the coal. The Deer Creek mine produced 3.006 million tons of coal using longwall methods and 0.742 million tons with continuous miners. The Trail Mountain mine produced 2.907 million tons of coal using longwall methods and 0.504 million tons with continuous miners.

Longwall production in the Deer Creek mine was within three panels on the West Side of the 3rd North B Mains. Continuous miner development was concentrated in the North Rilda area developing longwall panels in the northern-most reserves. Good quality coal was produced in most of the three longwall panels during 1998.

In the Trail Mountain mine, longwall production was in three longwall panels on the West Side of 5th left. The continuous miner sections developed future longwall panels to the north off the 5th left mains. Trail Mountain mine production was of sufficiently low ash for much of the year that the coal was shipped

directly to the Hunter Power plant, thus bypassing the preparation plant.

In March of 1999, PacifiCorp was the successful bidder for the Mill Fork coal lease tract containing 5,560 acres of coal land. Coal from this tract will be used to extend the life of the fuel supply for the Huntington and Hunter plants.

Canyon Fuel Company, LLC

As mentioned in the 1997 Utah Coal Production and Distribution Report, Arch Coal, Inc. participated in the ongoing consolidation of the U.S. coal industry by acquiring ARCO's domestic coal operations, including their 65 percent ownership in Canyon Fuel Company, LLC (CFC). That acquisition was completed effective June 1, 1998 and marked the second time in about 18 months that the former Coastal States Energy Co. mines had changed hands.

Consolidation in the coal industry continues at a rapid pace. Operations responsible for approximately one-third of the total U.S. production changed hands in 1998. (The ARCO acquisition by Arch equaled roughly 6% of the U.S. production.) Arch now supplies about 10% of total U.S. coal demand.

This acquisition, along with the other ARCO Western U.S. mines, greatly expanded Arch's reserve base of compliance and

low-sulfur coals. Two significant and fundamental changes in the domestic electricity marketplace allowed Arch to compete more aggressively: Phase II of the Clean Air Act Amendments and deregulation of the electric utility industry. The addition of the Western mines has allowed Arch to sell coal to virtually every major U.S. utility in 1998 and the firm should be well positioned to continue as a major supplier of compliance coal in the next millennium.

Early this year, CFC successfully resolved a long-standing contract dispute with Intermountain Power Agency (IPA) that pre-dated ARCO's acquisition of the three Canyon Fuel mines. Included in this settlement were negotiations to resolve the dispute with IPA and reach a mutual beneficial settlement resulting in a continuation of favorable pricing for coal shipped through 2001; an increase in tonnage commitments; an extension of the contract through 2010; a cash payment to Arch to pay down debt; and more flexibility in mine sourcing (allowing CFC the option to ship from lower-cost mines). With the new sourcing flexibility and a planned longwall installation at CFC's Dugout Canyon Mine, Canyon Fuel will reduce production at its higher-cost Skyline mine by almost 1 million tons in 1999 and will consider further reductions in 2000 and beyond. The IPA

contract will be sourced primarily from the lower-cost Sufco and Dugout Canyon mines.

Two other items of note occurred at CFC mines in the second half of 1998 and in early 1999. First, as noted above, the Dugout Canyon mine opened and is gearing up to install a longwall (first production from the longwall is expected by mid-2000). With the successful startup of Dugout Canyon, the old Soldier Canyon mine was phased out and closed prior to year-end. CFC expects that the Dugout Canyon Mine will eventually produce more than four million tons per year. Second, Sufco was the successful bidder on the BLM's Pines Tract. After having its first bid rejected by the BLM for economic deficiencies, CFC's revised bid for the approximately 60 million ton tract was successful. Production will begin on the new lease during the latter part of 1999.

White Oak Mining and Construction Company, Inc.

In 1998, White Oak produced 588,000 tons of clean coal from its No. 1 and 2 mines, since faulting makes access to both seams possible. Coal was shipped to Eastern and Western customers as well as to the export market. The coal was produced from both the Upper and Lower O'Conner seams out of the No. 1 mine.

Due to poor ground conditions encountered in the No. 2 mine during the summer of 1997, White Oak opened the No. 1

mine in September and idled the No. 2 mine in November, 1997.

Production continued into 1998 from the White Oak No. 1 mine until May, when the mine was closed and the operations were shifted back to the No. 2 mine in June, 1998. Production continued from that mine to the year's end. White Oak, subsequent to obtaining a lease modification in 1997, submitted a request to the Division of Oil, Gas and Mining for the inclusion of the newly obtained lease in the permitted area. In late 1998 White Oak considered it prudent to put up its Utah coal assets for sale. On July 16, 1999, Lodestar Energy Inc. of Lexington, Kentucky with an annual production of 10 million tons mostly from mines in West Virginia and Kentucky purchased all the assets of White Oak Mining and Construction Company in Utah including the Horizon mine and some interest that the Japanese coal traders held in the operation. The Lodestar will be the owner and the operating company for both White Oak and Horizon but the mines would be referred to as the White Oak No. 1 and No. 2 and Horizon mines.

Horizon Mining, LLC

Horizon Mining, LLC was formed in August 1997 to operate the Horizon Mine which is located in Consumers Canyon near the site of the old mining operations of the Blue Blaze and National mines. Horizon continued operation and developed first north main, however, it encountered large amounts of

water infiltration which necessitated halting coal production. Horizon then rehabilitated the Blue Blaze mine to the southwest which was uphill from the Horizon mine. Development to the southwest was temporarily stopped. During 1998, Horizon produced 106,000 tons of coal. Horizon ceased coal production operation in March 1999. All the mine assets, reserves and leases were sold to Lodestar Energy on July 16, 1999. Production from the Horizon mine is expected to restart in late 1999 or early 2000.

Andalex Resources, Inc.

Andalex concentrated its effort in 1998 on development and production of coal from the Aberdeen mine and the design and permitting of the West Ridge mine.

The Pinnacle mine and the Apex mine remained inactive during 1998. All of Andalex's effort was directed toward production from the Aberdeen mine which at this time is under 2,400 to 2,700 feet of cover. Three continuous miners, working a total of five shifts per day, were used for the development of gate roads and mains. A longwall working two shifts per day was used to produce the main bulk of coal. Andalex's production in 1998 amounted to 1.76 million tons of coal. The longwall panel was moved once during 1998 which was in February. In March of 1999 it was moved again. This panel contains slightly more than two million tons of coal and the longwall may not need moving

until May of 2000. Wildcat load-out had a throughput of more than 2.9 million tons including more than one million tons from Genwal. Andalex accomplished all that with a work force of 120 including several part-time and student workers.

The Westridge mine project which is co-owned by Andalex and IPA is on schedule. The 8.5 mile road to the mine site has been completed and it is being paved. The work for surface drainage culverts is near completion and the 46 kilovolt (kv) power line is in the process of being built. Major earth work associated with the surface facilities has been completed and the top soil has been set aside. The surface facilities should be completed by this fall and soon after, development mining should begin. The actual longwall operation is expected to begin in early 2001.

Genwal Resources, Inc.

The Crandall Canyon mine, operated by Genwal Resources, Inc., experienced its first full production year in 1998 after purchasing a new longwall and expanding the surface facilities in 1997. Genwal coal produced 3.52 million tons of coal, compared to 2.66 million tons in 1997. Production comes from a longwall unit and two continuous miner units. One miner unit develops the gate entries for the longwall, and the other develops the main entries and sets up the gate roads.

In 1998, Genwal Resources, Inc., with a roster of hard work-

ing and dedicated employees, helped Genwal to be one of the safest and highest productivity mines in the nation. The accident incident rate for 1998 was 6.59 versus the industry rate of 11.77. Productivity was reported at 80.79 tons per man day for 1998.

For 1999, Genwal has set goals to continue its success in the coal industry. Genwal's existing production capability will guarantee safety, high productivity, and maximum recovery of reserves.

Co-op Mining Company

Co-op Mining Company was started in 1940 and has operated continuously for the past 58 years. Co-op is an independent coal producer of lower sulfur, high Btu coal and operates in the Bear Canyon near Huntington, Utah. Annual production in the last several years has been 400,000 to 500,000 tons per year with the 1999 tonnage projected to be approximately 700,000 tons. Co-op's marketing has been directed at industrial consumers, households and Utah & Nevada utilities, with additional tonnage sold to the Midwestern market east of the Mississippi.

Co-op controls in excess of 30 million tons of coal reserves consisting of private, fee and federal coal, of which approximately 75 percent of the reserves are private and fee coal. The reserves are located east and west of Bear Canyon though current mining operations are west of Bear Canyon.

There are three minable seams on the property. These include the Tank, Blind Canyon, and Hiawatha Seams. The Tank Seam is the top seam, the Blind Canyon Seam the middle, and the Hiawatha Seam the bottom. Co-op is presently mining in the Tank Seam. Seam thickness varies between 12' - 20' in the Blind Canyon, 5' - 9' in the Hiawatha and 8' - 10' in the Tank Seam. Bear Canyon mine operates continuous miners and shuttle cars, and has the capability to run three sections. Currently two sections are in operation. Present mining equipment would allow production of up to 1 million tons per year.

A modern screening facility, which allows participation in the industrial market for oil treated stoker and household coal, has been installed at the mine site. Co-op has the ability to ship unit-train shipments of up to 120 cars. The facility is designed to load 100 cars in less than 2 hours.

Cyprus Plateau Mining Company

Cyprus Plateau Mining Co. continued to produce coal from its two Utah operations in 1998. Both the Star Point No. 2 mine and the Willow Creek mine produced high quality steam coal product for the western U.S. and Pacific Rim export markets.

The Star Point operation, located in the Wasatch Plateau Coal Field, produced from two continuous miner sections in the Middle Seam. All production

was shipped raw.

Initial longwall production at the Willow Creek mine, located in the Book Cliffs coal field, commenced in August and retreated approximately 2,100 feet before a disastrous mine fire occurred on the evening of November 26th. The mine was safely evacuated and the portals were sealed within a matter of hours of the fire's discovery. Because of the rapid isolation of the mine atmosphere, the fire was quickly extinguished. Injection of CO₂ through various holes drilled near the fire site further cooled and smothered the ignition source. Mine crews were sent to the Star Point No. 2 mine to supplement production while the Willow Creek recovery efforts were underway.

As a result of an aggressive recovery action plan, re-entry of the mine was underway within two weeks of sealing. Mine recovery teams found that the fire damage was chiefly restricted to return airways within 1,000 feet of the suspected source. The longwall face and other major mining equipment was not damaged. Full scale continuous miner production resumed in April, 1999.

Drilling and mining experience underground during the year, resulted in the projection of additional longwall panels in the D Seam zone, the development of surface gob vent boreholes to enhance ventilation, and the addition of coal leases to the west.

In October, Cyprus Amax Minerals Co. announced the possible sale of Cyprus Amax Coal Co. which includes all its U.S. coal properties. RAG International Mining Company based in Essen, Germany, which is an international energy and technology company with 104,00 employees worldwide, made an offer of \$1.05 billion for all the firm's coal holdings in May of 1999.

Coal Leasing Activity in Utah

Horizon Coal Co.

During 1998, there was only one coal lease sale in Utah. On August 10, 1995, Horizon Coal Corporation of Wise, Virginia applied for an LBA covering an area of 1,280 acres in Township 13S and Range 8E, covering all or parts of sections 6, 7, 8, 17 and 18, containing 8 million tons of coal. The National Environmental Policy Act (NEPA) compliance document for Beaver Creek Tract was prepared by a third party contractor.

In a public auction which was held on May 14, 1998 for the sale of 1,288.49 acres of Beaver Creek Track, Horizon Mining LLC's bid of \$315,000 was accepted. The lease which was offered for sale was located in Carbon County, Utah, approximately 15 miles northwest of Price, Utah and was delineated as follows:

T, 13 S., R. 8 E., SLM, Utah
Sec. 6, SESW, S2SE, NWSE;
Sec. 7, lots 1-3, E2, E2W2;
Sec. 8, SWNE, NWNW, S2NW,
N2SW, SWSW, W2SE;
Sec. 17, N2NW, SWNE;
Sec. 18, NENE.
Containing 1,288.49 acres

One economically recoverable coal bed, the Hiawatha Seam is found in this tract. The seam averages 6.7 feet in thickness. This tract contains an estimated 6.3 million tons of recoverable high volatile B bituminous coal.

The lease was sold at \$245 per acre or \$.05 per recoverable ton. This lease was essential for Horizon as their previous lease

holding was sufficient for only one year of operation. Now the firm can operate for 10-15 years during which they can build up their reserve base by purchasing more federal coal leases.

Genwal Coal Co.

On February 4, 1993, Genwal Coal Company, which is now a 50/50 subsidiary of Intermountain Power Agency (IPA) and Andalex Resources, filed an LBA for 4,051 acres of federal coal leases covering all or parts of sections 1, 10, 11, 12, 13, 14 and 15 of Township 16S and Range 6E and sections 6, 7 and 8 of Township 16S and Range 7E, called Mill Fork Canyon, on land adjoining its presently operating mine and the previously purchased LBA. Since there was some unleased federal coal east and south of Genwal's application area that should have been added to the LBA to avoid a bypass situation, the Tract Delineation Team considered it prudent to add these areas to the tract being offered for auction. Originally Genwal did not include this area in its LBA because of the quality of coal, seam thickness and possible environmental concerns associated with hydrology and escarpment protection existing in the area. Studies conducted by the Forest Service in years previous to the submission of the application concluded that the aforementioned land could be leased. The environmental

analysis for the tract based on the presently available information will determine the feasibility of leasing the delineated tract. The final delineated tract contained 6,442.82 acres covering all or parts of sections 1, 10, 11, 12, 13, 14, 15, 22, 23 and 24 of Township 16S and Range 6E and sections 4, 5, 6, 7, 8, 9 and 18 of Township 16S and Range 7E, containing 58.7 million tons of recoverable coal in the Blind Canyon Seam and the Hiawatha Seam.

This tract, which was part of the land exchange agreement unveiled on May 8, 1998 by Secretary of the Interior Bruce Babbitt and Utah Governor Michael Leavitt, went out for bid on March 30, 1999. Even though Andalex was the nominating party and submitted a bid of \$18.2 million corresponding to about \$0.31 per ton, the lease was sold to Utah Power (PacifiCorp Electric Operation), which was the highest bidder with an offer of \$25.2 million corresponding to \$0.43 per ton.

PacifiCorp Electric Operations

PacifiCorp Electric Operations (Utah Power) of Salt Lake City submitted an LBA on February 26, 1991, for 7,864 acres in the North Trail Mountain/Cottonwood Creek area of Wasatch Plateau coal field in Emery County covering all or parts of sections 2, 3, 4, 9, 10, 11, 14, 15, 16, 21, 22, 23, 24,

25, 26, 27, 28, 29, 32 and 33 of Township 17S and Range 6E. This application is in full conformity with responsible and prudent coal operation.

In reviewing this LBA the Tract Delineation Team noted some areas where adjustments could be made in the tract configuration. The western edge of the tract in some areas was identified by the Forest Service in their forest plan as being unsuitable for coal leasing because of the need to protect the escarpment along Joe's Valley. However, they recommended the inclusion of additional land to fill the gap left between the LBA and their existing leases. As a result the recommended tract by the Tract Delineation Team the Cottonwood Canyon Tract shall include all or parts of sections 2, 3, 4, 9, 10, 11, 12, 13, 14, 15, 16, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 32 and 33 in Township 17S Range 11E, in total 9,243.87 acres containing 75 million tons of recoverable coal. The two areas of concern prior to going out to bid would be the determination of the area of surface disturbance which has to be resolved with the Forest Service and the inherent problem of being near a reservoir (in this case Joe's Valley) which has to be resolved with the Bureau of Reclamation. This should not take more than two years.

Canyon Fuel Company, LLC

On December 16, 1996, Canyon Fuel filed for an LBA covering an area of 5,858 acres of federal coal leases named

"the Pines" in the Wasatch Plateau coal field. The requested lease contains some 50 million tons of coal existing in all or parts of sections 35 and 36 of Township 20S and Range 5E, and sections 1, 2, 3, 10, 11, 12, 13, 14, 15, 22, 23, 24, 25 and 26 of Township 21S and Range 5E. Delineation of the tract which was completed contained 60 million tons of recoverable coal in all or part of Section 35 and 36 of Township 20S and Range 5E, Sections 1, 2, 10, 11, 15, 22, 23, 25 and 26 of Township 21S and Range 5E and Sections 19 and 20 of Township 21S and Range 6E. This lease went out for bid on April 15, 1999. The sole bidder was Canyon Fuel which submitted a bid of \$13.3 million corresponding to about \$0.22 per recoverable ton of coal. This bid was rejected by the BLM since it did not meet the fair market value of the coal as determined by the BLM. Five weeks later, on May 20, 1999, another sale for the same tract was held with Canyon Fuel being the sole bidder again. The \$16.9 million bid which corresponded to \$0.282 per ton was accepted by the BLM.

Also, in 1998, Canyon Fuel Company LLC also submitted a lease by application for 2,612 acres of federal land known as the Flat Canyon Tract. The lease covers all or parts of Sections 21, 28 and 33 of Township 13S, Range 6E and all of Sections 4 and 5 of Township 14S Range 6E. Delineation for this tract was completed by end of June 1999

and work on National Environmental Policy Act compliance should start soon after. There is a good chance that this LBA will be offered for sale by the end of 2000.

Andalex Resources, Inc.

During March 1997 Andalex Resources purchased B Canyon coal reserve from BP America, a British Petroleum subsidiary, and started the process of permitting the mine. Andalex plans to have the mine producing coal in the year 2000 from a longwall operation which should be producing at a minimum rate of 3 million tons per year. B Canyon reserve (renamed West Ridge) should increase Andalex's reserve of recoverable coal by at least 40 million tons.

AMCA Coal Company, the leasing agent for Andalex Resources, filed for an LBA in July 1997 for 1,600 acres of federal coal lease property existing in all or parts of sections 1, 3 and 12 of Township 14S and Range 13E, and sections 6, 7 and 18 of Township 14S and Range 14E, and section 35 of Township 13S and Range 13 E, containing some 10 million tons of recoverable coal. This LBA which was called Bear Canyon and later was renamed West Ridge, is adjacent to the above mentioned lease. The BLM is now collecting baseline data and consulting with Andalex to find the best way to accomplish NEPA compliance. The sale of this tract is still in the distant future.

On May 20, 1998 Andalex

Resources Inc. submitted its final version of emergency lease by application for 462.73 acres of federal land by the name of Summit Creek Tract. This land is contiguous with an existing federal lease held by Andalex covering all or parts of Sections 29, 30, 31 and 32 of Township 12S and Range 11E. This LBA was withdrawn by Andalex in early 1999.

Outlook for Utah's Coal Industry

FORECAST FOR 1999

Prices

Over the past 14 years, coal prices in Utah have declined. In 1984 Utah coal, on average, sold for \$29.20 per ton. During 1998, the same coal sold for \$17.83 per ton. This represents a decrease of 39 percent in current dollars, but a decrease of almost 59 percent on a constant dollar basis. Again, on a constant dollar basis, the comparison is even greater with 1976 prices when coal sold for more than 300 percent of the 1998 price. In other words, the decrease was more than 68.6 percent.

From 1990 to 1993, average prices have fluctuated around \$21 per ton and hit a new low of \$20.07 in 1994. In 1995, another new low was established at \$19.11 then another one in 1996 at \$18.50 followed by yet another one at \$18.34 in 1997 and finally still another low in 1998 at \$17.83. Even though this appears to be a decline in coal prices, in reality, it is not.

The increase in sales occurred mostly in markets which were at the lower end of the price scale while some reduction of delivery occurred in markets which were at the upper end of the price scale. This, therefore, indicates a possible "bottoming out." In the near term, the average price will

most likely remain stable. For 1999, the average price of coal will probably be about \$17.91 per ton.

The average spot price of coal stood at \$14.33 during 1996, having fluctuated between \$13.50 and \$15.07, then started to rise during the

some softening of the spot prices, though it is unlikely to go below \$16.35 per ton.

Skyline production could decrease by more than 10 percent. White Oak's production could experience some decrease and Horizon Coal would continue the status quo.

Utah Coal Prices

1999 value is forecast

first quarter of 1997, and ended the year at \$16.63 per short ton for an average value of \$16.51. During 1998, spot prices stayed around \$16.63 and finished the first quarter of 1999 at the same level. The firming up of the spot price had more to do with the supply than demand.

During 1999 Utah coal production will likely increase by 1.0 million tons, from 26.6 to 27.6 million tons. This could lead to

Soldier Canyon mine would continue its standby status as production from the Dugout Canyon mine increases. If Dugout Canyon manages to hold production costs down, which is likely, then production at Dugout Canyon could exceed the levels experienced at Soldier Canyon. Plateau, Andalex and Co-op should experience a moderate increase in production while Sufco and Genwal's production

will level off and may even decrease to some extent.

The current dollar prices will continue a slight downward trend for maybe another two years as some of the other higher price contracts either run out or are renegotiated. However, the price of coal as measured in constant dollars is expected to continue to fall for a longer period. In other words, even though the average dollar price per ton will start to accelerate in two years, the rate of increase at that time should not exceed that of inflation.

Utah's spot coal price changes are not only a function of demand changes or Utah's coal supply but also a function of the availability of coal in the neighboring states, more importantly Colorado. Just as much as Cyprus' Twenty Mile mine production problems contributed to the tightening of Utah's spot prices in 1996, an existence of over supply in Colorado could play a part in softening the spot price of Utah coal.

It is important to bear in mind that Utah's coal prices are also influenced by the world price of coal. The correlation may not be high, but the existence of a strong influence cannot be denied. During 1996 world coal prices remained relatively flat but started to fall off in 1997. Coal operators in Utah agreed to a concession of one-dollar-plus per ton. In 1998 there was another concession of about one dollar per ton of

coal exported to the Pacific Rim countries of Japan and Korea. However, the contract with Tai-power may be such that the concession made to Japanese coal importers would not affect it materially. Other countries such as Australia and South Africa gave concessions ranging up to \$3.00 per tonne (metric ton).

Even though the Australian exporters may have given concessions amounting to \$3.00 per tonne this may not be as severe as it seems because all export contracts in Japan are written in U.S. dollars. As Australian dollars devalue with respect to U.S. dollars, the amount of Australian dollars received from the Japanese importers' increases, thereby defraying the effect of the previously agreed upon concession. If the FAS price of Australian coal goes from \$37.00 to \$34.00, but the Australian dollar devalues by 9 percent, the actual Australian dollar received by the coal mines will be greater than before.

Though export prices for Utah producers were not a determining factor in overall coal prices, and the sale takes place on marginal production, it should be realized that as the amount and the percentage of the exported coal relative to total production increases, the effect of the export price on the average price of coal becomes more relevant. However, over the past two years the level of exports as well as the percentage of the production has

been on the decline, which means the export prices had less influence on the actual price of coal.

Other factors also tend to soften prices. Technological developments in coal production and handling continue to lower the break-even point for production and to reduce prices overall. Large volume production allows operators to reduce profit margin per ton by lowering prices and still keep overall profits high. The abundance of coal supply on the international market will continue to exert pressure on Utah producers to keep prices competitive.

World recoverable coal reserves stand at 1.126 trillion tons. World production and consumption is around 5 billion tons per year implying that, at the present rate of consumption, the world has an adequate supply for the next 225 years. This, of course, is based on the recoverable reserves that are known and reported at this time. There are many coal reserves that remain undiscovered and some that are discovered but not reported or are under reported.

There is also some question about the "recoverable" fraction of the recoverable reserves. By "recoverable" we refer to resources that we can mine efficiently with today's technology. However, future technology may allow a greater percent of the resource to be recovered, hence a much greater

recoverable reserve.

The rate of consumption also directly affects the remaining number of years of supply. As the world's population increases the demand for energy, including coal, will increase. As developing countries with high growth rates expand and add energy-intensive industries, the demand for energy and coal will increase in tandem. Presumably, at the same time, new technologies will help us achieve much greater efficiency in our energy conversion. Today, on average, we burn 10,080 Btu (0.84 lb. of 12,000 Btu per pound of coal) to generate 1 kWh of electricity which has 3,413 Btu. In other words, in the process of conversion we lose 6,667 Btu or 66.1 percent and end up with 33.9 percent of the energy used. Sierra Pacific's Pinon Pine Power Project is now operating at about 40 percent efficiency. By the first decade of the next century, many of our energy conversion units will have a heat rate of 6,800 Btu/kWh or slightly more than 50 percent efficiency. This, in reality, means that by the first decade of the next century we should be able to use the same amount of coal to generate 50 percent more electricity than we do today, implying that our reserve-to-production ratio will increase, thus extending the life of our reserves. This leads to the conclusion that the world has a vast coal reserve and this supply overhang will ultimately keep the supply up and the price down.

On the other hand, there are also other forces acting to raise coal prices, specifically western coal. As we approach the year 2000, when the second phase of the Clean Air Act Amendments of 1990 becomes effective, we will experience a renewed wave of interest in low sulfur coal throughout the country. The Utah coal market should see some tightening during the summer and as we move into fall. Utah's coal production, now at the upper percentage of capacity, should respond to the greater demand by showing some firming up in the price of coal.

Production

Utah coal production for 1999 will surpass 27.5 million tons, reaching an all-time high in the industry's 130-year of recorded history. Three factors will account for the record: 1) greater steam coal consumption by the electric utilities in Utah; 2) greater level of exports; and 3) increased industrial consumption of the coal in the west.

Electric utilities in the west as well as electric utilities in the Utah will continue using greater amounts of Utah coal in the future. In 1999, shipments of coal to electric utilities in the west will increase by 18 percent while shipments to the east will go down by as much as 34 percent. In addition, shipment to Pacific Rim countries will increase after the first full year of operation of the \$200 million expansion of the Port of Los Angeles Dry Bulk Terminal.

Distribution

During 1999, distribution of Utah coal most probably will surpass 27.3 million tons while production will top 27.5 million tons. Distribution of electric utility coal to out-of-state customers will decrease by as much as 0.4 million tons from 7.7 to 7.3 million tons.

On January 1, 1995, TVA and White Oak Mining and Construction Company, Inc. signed a ten year contract for annual delivery of 1.5 million tons. Another 10-year coal contract for delivery of 0.5 million tons per year was signed on the same date between TVA and Genwal Coal Company. This was the first time in a decade that Utah coal started to flow to electric utilities in the east on a long term basis even though numerous spot sales had been made to that sector of the country.

This 2 million tons of additional coal through 2005 was a boost to Utah's coal production. It will lead to more jobs in Utah's coal industry as well as many indirect jobs in local communities. In addition to TVA, Utah now has two companies sending coal to two electric utilities in Illinois. Our forecast for the first decade of the 21st century shows that electric utility coal going east should be above 4 million tons per year.

Distribution of Utah coal to electric utilities within the state should show very little year-to-year change, unless new facilities are built or some of the

older units are retired. Currently, there is no indication that either will happen. Older units experience more down-time due to maintenance and repair, so on the basis of this reasoning a slight decrease in distribution may be expected; on the other hand, companies could increase their electric generation marginally by ramping up their operation. As a combined result, of these two factors a slight increase in consumption is expected. The only unit that could materially affect electric utility coal consumption within the state is Intermountain Power Agency's IPP plant. During years with higher precipitation in the Pacific Northwest, more hydropower becomes available at costs below those of coal. This will, to some extent, curtail the operation of IPP units resulting in less consumption of Utah coal. For 1999, this unit may purchase and burn about 0.2 million tons more than it did in 1998, even though we are expecting to have an above average run off this summer. PacifiCorp distribution will also increase by just under 1 million tons while the consumption of coal and generation of electricity at the plants increases. DG&T's Bonanza plant is not forecasted to use any Utah coal in 1999. During the first decade of the next century, the electric utility sector's consumption of Utah coal within the state should increase from 12.8 in 1998 to close to 14.0 million tons per year.

Distribution of Utah industrial coal within and outside the

state during 1999 will increase marginally, increasing also slightly in the future as only out-of-state consumption increases. This trend should continue through the first decade of the 21st century.

Distribution to the residential and commercial sector will also increase during 1999 by 30 percent. However, any future movement in this consuming sector is ultimately tied to the price of natural gas. Some commercial operations may begin switching from natural gas to coal which should result in increased consumption.

Finally, in the export market during 1999, distribution will increase by about 10 percent, or just under 0.33 million tons to 3.0 million tons. The forecast for this consuming sector for the first decade of the next century is above 4.5 million tons per year.

The general outlook for Utah's coal industry is bright despite some coal operators having moved their operations to other states, sold, or otherwise disposed of their Utah coal properties. Still we have seen a number of companies expand operation and double in size within a span of three or four years. Many companies have applied for new federal coal leases, indicating continuing interest in Utah's coal reserves. During 1996 two mines opened up while three mines closed. In 1997 four mines opened up and one mine closed and finally during 1998

one mine opened and one mine closed. This likely is the beginning of many more mines opening in Utah as some of the older mines curtail operation and relocate to new locations.

Coal production in Utah has enjoyed steady growth since the mid-1980s and has more than doubled in size within the past decade. Despite coal prices that have declined steadily for a decade, coal production in Utah has increased. This is indicative of a strong and healthy coal industry.

In 1999, all consuming coal sectors within and outside of Utah are expected to have moderate growth. The coal contracts with eastern utilities should add permanence to electric utility consumption outside of Utah. The forecast of total production for the first decade of the 21st century is about 31 million tons.

Federal, Legislative, and Other Issues

Los Angeles Export Terminal, Inc.

Los Angeles Export Terminal, Inc. ("LAXT") was incorporated in 1993 and opened its \$200 million plus facility for the export of coal and petroleum coke in November, 1997. This unique privately held corporation, with 35 shareholders representing both American and Japanese interests, is located in California at the Port of Los Angeles. All shareholders are associated with the coal export chain and are producers, shippers, financial institutions, Japanese trading houses, constructors or end users and consumers. This new and environmentally sensitive state-of-the-art facility is capable of exporting approximately 9 million metric tons of coal and 1.8 million metric tons of petroleum coke annually. The LAXT facility is capable of loading a standard Panamax vessel within one day and loading a Cape-sized vessel within two days under normal conditions. LAXT's berth is designed to accommodate 250,000 DWT vessels and is dredged to 72 feet. LAXT, arguably the most technologically sophisticated coal terminal in the world, provides coal producers in the western U.S., in particular Utah, with a gateway to the Pacific Rim.

The LAXT facilities are operated under two separate

operating agreements, the Terminal Operating Agreement and the Stevedoring Services Agreement. The terminal operator, Savage Pacific Services, responsible for managing and operating the receipt and storage of coal and petroleum coke, has its corporate offices in Salt Lake City, Utah. Kinder Morgan Bulk terminals, Inc. is responsible for managing and operating the shiploading facility at the berth.

LAXT has completed its first full fiscal year (July 1, 1998 through June 30, 1999) handling the export of approximately 2.4 million metric tons of coal and approximately 1.6 million metric tons of petroleum coke. Although these numbers reflect the current market conditions in the Pacific Rim, it is anticipated that the volume of export for the 1999-2000 fiscal year will increase substantially at the LAXT facility.

Utah Schools and Land Exchange Act of 1998

Public Law 105-335

The land exchange agreement which was unveiled on May 8, 1998 by Secretary of the Interior Bruce Babbitt and Utah Governor Michael Leavitt was indeed a long awaited one. It was, no doubt, the designation of the Grand Staircase - Escalante National Monument by President Clinton on September 18, 1996 that gave the

additional impetus to culminate this long-awaited federal government/ state land exchange.

This agreement encompasses the exchange of state land, tribal land, federal land, mineral rights on state land, tribal land, federal land as well as royalties on minerals and lump sum payment in cash. As part of the exchange the federal government will receive:

- \$177,956.72 acres of surface and mineral state holdings and an additional 24,001.03 acres of mineral-only properties captured within the Grand Staircase - Escalante National Monument;
- 69,688.93 acres of surface and mineral property captured in Arches National Park, Capitol Reef National Park, Dinosaur National Monument, Glen Canyon National Recreation Area, and Flaming Gorge National Recreation Area;
- 45,241 acres of surface and mineral properties captured in the Navajo and Goshute Indian Reservation;
- 70,106.71 acres of surface and mineral property captured within Wasatch - Cache National Forest, Sawtooth National Forest, Ashley National Forest, Uintah National Forest, Manti-La Sal National

Forest, Fishlake National Forest, Dixie National Forest, and Desert Range Experimental Station; and,

- Four tracts in the Alton Coal Field tracts previously designated unsuitable for mining (these lands are already accounted for in the Grand Staircase - Escalante National Monument acreage totals) for a total of 366,095 acres of land plus an additional mineral rights covering 66,479.27 acres.

The state of Utah on behalf of trust lands administration will receive:

- \$50 million in cash;
- \$13 million (1998 dollars) payable out of the federal share of royalties from future coal sales at the Cottonwood Coal tract;
- 597.76 acres (surface and minerals) at the Blue Mountain telecommunications site in Uintah County
- 2,998.63 acres (surface and minerals) in and around the Beaver Mountain Ski Resort;
- 1,920.00 acres (surface and minerals) at the Warner Valley tract, acquired primarily for surface development;
- 34,248.30 acres (surface and minerals) at the Big Water tract, acquired primarily for surface development;
- 12,797.50 acres (surface and minerals) at the Hatch tract, acquired primarily for surface development;

- 58,608.65 acres (surface and minerals) at the Ferron tract, containing an estimated 2 billion tons of in-place coal resource and 185 billion cubic of recoverable coal bed methane gas;

- 881.01 acres (surface and minerals) at the West Ridge tract, containing an estimated 4 million tons of recoverable coal;

- 2,228.96 acres (surface and minerals) at the Millar County tract, containing valuable limestone resources;

- 4,004.30 acres (surface and minerals) at the Duchesne County tract, containing speculative oil and gas potential;

- 2,600.76 acres (surface and minerals) at the Uintah County No. 1 and No. 2 tracts, containing speculative tar sands deposits;

- 5,562.82 acres (mineral only) at the Mill Fork tract, this property will revert to federal control after 22.3 million tons of coal are produced and sold from the tract;

- 9,597.02 acres (mineral only) at the North Horn tract, this property will revert to federal control after 100 million tons of coal are produced and sold from the tract; and,

- 5,113.84 acres (mineral only) at the Muddy and Dugout Canyon tract which will revert to federal control after 34 million tons of coal are produced and sold from the tracts.

Grand Total: \$63 million, 120,885.87 acres of developable surface and mineral lands in addition to 20,273.68 acres of known mineral-only properties.

In addition to the surface real estate development potential of the acquired lands, the properties are estimated to contain in excess of 185 billion cubic feet of recoverable coal-bed methane, 160 million tons of recoverable coal, in-place coal resources in excess of 2 billion tons, valuable limestone resources and other speculative mineral assets.

This bill was sponsored by Utah Rep. James Hanson and introduced into the House on May 12, 1998. Two of the five cosponsors were also Utah Reps. Merrill Cook and Christopher Cannon. The bill passed the house by voice vote on June 24, 1998 and was sent to the Senate. This bill was referred to the Committee on Energy and Natural Resources on June 25, 1998 and to the Subcommittee on Forests and Public Lands on June 26, 1998. After going to the senate in September the bill was finally passed and was signed into law on Oct. 31, 1998.

Sunnyside Power Plant

Kaiser Steel Corp. as early as 1986 had plans to build a qualifying facility to utilize its coal refuse pile as was detailed in 1980 Federal Energy Regulatory Commission (FERC) order pursuant to Section 201 of the 1978 Public Utility Regulatory

Policies Act (PURPA) which actively encourages small power production in the country. When in 1988 Kaiser Steel Corp. and its subsidiary Kaiser Coal Company filed for bankruptcy, Sunnyside Salvage and Reclamation Company of Boulder, Colorado was formed to acquire the Sunnyside property of Kaiser Coal Company, which it did in 1989.

Sunnyside Coal Company operated successfully until February 1994 when its coal supply contract with Geneva Steel ran out and was not renewed.

Among the assets that Sunnyside Coal acquired from Kaiser was a 10 million ton plus coal refuse pile that had been accumulated over more than half a century. This refuse pile was both an asset and a liability. If nothing was going to be done with the pile, Sunnyside Coal Company had to remove it to meet federal reclamation regulation when the firm was going to stop operation. This dilemma was to some extent alleviated when the Environmental Power Corp. (EPC) of Delaware formed a Utah subsidiary by the name of Sunnyside Power Corp. to take over Kaiser's plans for qualifying facilities and Sunnyside Coal Company's refuse pile to build a facility that would generate electricity. The land that the coal refuse pile was sitting on was purchased for \$1.2 million.

After four years of planning, preparation, negotiation, capital-

ization and construction, Sunnyside Power Company started generation of electricity in 1993. This plant now utilizes between 300,000 to 350,000 tons of material from the refuse pile which was accumulated on the fee land and was subsequently conveyed by Kaiser Coal Company to Sunnyside Reclamation and Salvage Company. Later the land that it sits on was sold to Sunnyside Power Co.

The consumption of the refuse pile to generate electricity by an independent company as part of PURPA, which created a regulatory framework for encouraging electricity generation by renewable energy producers and cogenerators, was not considered by this office at the time as a coal operation for the following reasons:

- 1) It was difficult to determine when the original coal was mined and from what leases. The majority of leases which were used in mining were privately held, some were federal leases and part of these leases bordered state leases. Therefore, it was very difficult, if not impossible to determine with any degree of accuracy from which lease the coal that was being used had come from.

- 2) The coal was stored on private land and not federal land.

- 3) The refuse pile was not directly sold as fuel to be used for a specific purpose.

- 4) The refuse pile was owned by Sunnyside Power

Company and was consumed without changing hands to determine the price per ton of the fuel which was consumed.

- 5) When the land which the refuse pile sits on was purchased by Sunnyside Power Company it was not clear how much of the actual money that changed hands was for the land, how much for the refuse pile which was to be used as a fuel, or how much was for the rent of the land which was used to store the refuse pile upon thus, it became extremely difficult to put a price on the present value of the refuse pile as a fuel source.

- 6) The ownership of the refuse pile had changed hands. If there were any royalty to be collected it should have taken place when the land and the pile were sold by the original owner. Now that the power plant is burning the refuse pile, which it has already obtained and owns, it is difficult to collect the royalties.

- 7) Finally, the amount of money that changed hands for the price of the land (\$1.2 million), if it were for the value of the refuse pile, would make it about \$.11 per ton which makes the royalty value for the refuse pile less than \$.01 per ton, something that may not be economical to assert, assess, monitor and collect a royalty on.
